

Computer System B

Dr. Alma Oracevic
alma.oracevic@bristol.ac.uk

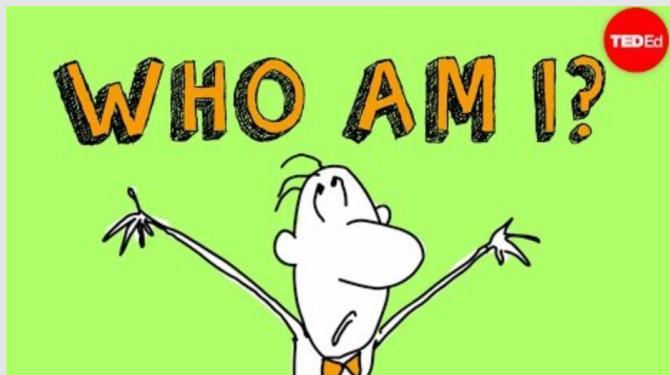

bristol.ac.uk

PhD – WSN security

Research on network security, malware security

Teaching: Network security, Ethical hacking

Dr. Sana Belguith

Guest Lecturers:

Ross Bevington - Head of
Deception for Microsoft),

Dr. Barney Craggs (Chief
Information Security Officer UoB),

Dr. Joseph Hallett (Lecturer UoB)

Syllabus CSB

- **Intro to general security**
- **Intro to Network Security**
- **Network Security**
- **Web Security +Firewalls**
- **Private networks**
- **Intro to Software Security**
- **Intro to OS +File System**
- **Memory management**
- **Large org in real world***

The Exam

- Final exam is 100% of the grade!
- Everything we cover (lectures, labs, exercises) is a part of the exam!

Today!

- Motivation for Cybersecurity
- CIA
- Authentication
- Authorization
- Accountability

bristol.ac.uk

What is
cybersecurity?

Computer Security

- The NIST *Computer Security Handbook* defines the term computer security as:

“the protection afforded to an automated information system in order to attain the applicable objectives of preserving the integrity, availability and confidentiality of information system resources”

(includes hardware, software, firmware, information/data, and telecommunications)

Why do we need cybersecurity?

Oops, your important files are encrypted.

If you see this text, then your files are no longer accessible, because they have been encrypted. Perhaps you are busy looking for a way to recover your files, but don't waste your time. Nobody can recover your files without our decryption service.

We guarantee that you can recover all your files safely and easily. All you need to do is submit the payment and purchase the decryption key.

Please follow the instructions:

1. Send \$300 worth of Bitcoin to following address:

1Mz7153HMuxXTuR2R1t78mGSdzaAtNbBWX

2. Send your Bitcoin wallet ID and personal installation key to e-mail wowsmith123456@posteo.net. Your personal installation key:

If you already purchased your key, please enter it below.
Key:

CYBER SECURITY

Disaster recovery

Taxonomy of security goals

CIA Triad

Computer Security Objectives

Confidentiality

- Data confidentiality
 - Assures that private or confidential information is not made available or disclosed to unauthorized individuals
- Privacy
 - Assures that individuals control or influence what information related to them may be collected and stored and by whom and to whom that information may be disclosed

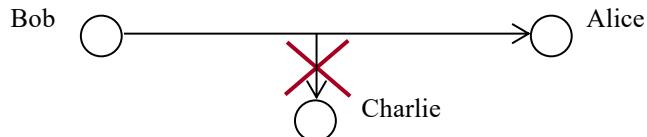

Integrity

- Data integrity
 - Assures that information and programs are changed only in a specified and authorized manner
- System integrity
 - Assures that a system performs its intended function in an unimpaired manner, free from deliberate or inadvertent unauthorized manipulation of the system

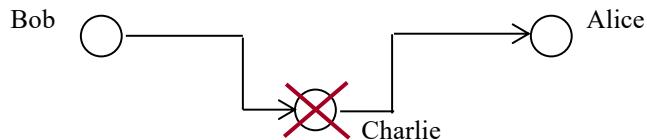

Availability

- Assures that systems work promptly and service is not denied to authorized users

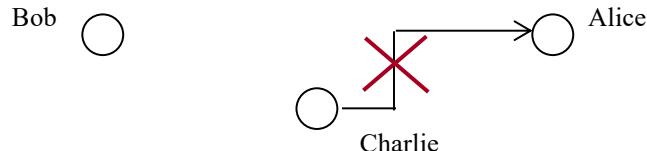

1. Confidentiality

2. Message integrity

3. Message authentication

Possible additional concepts:

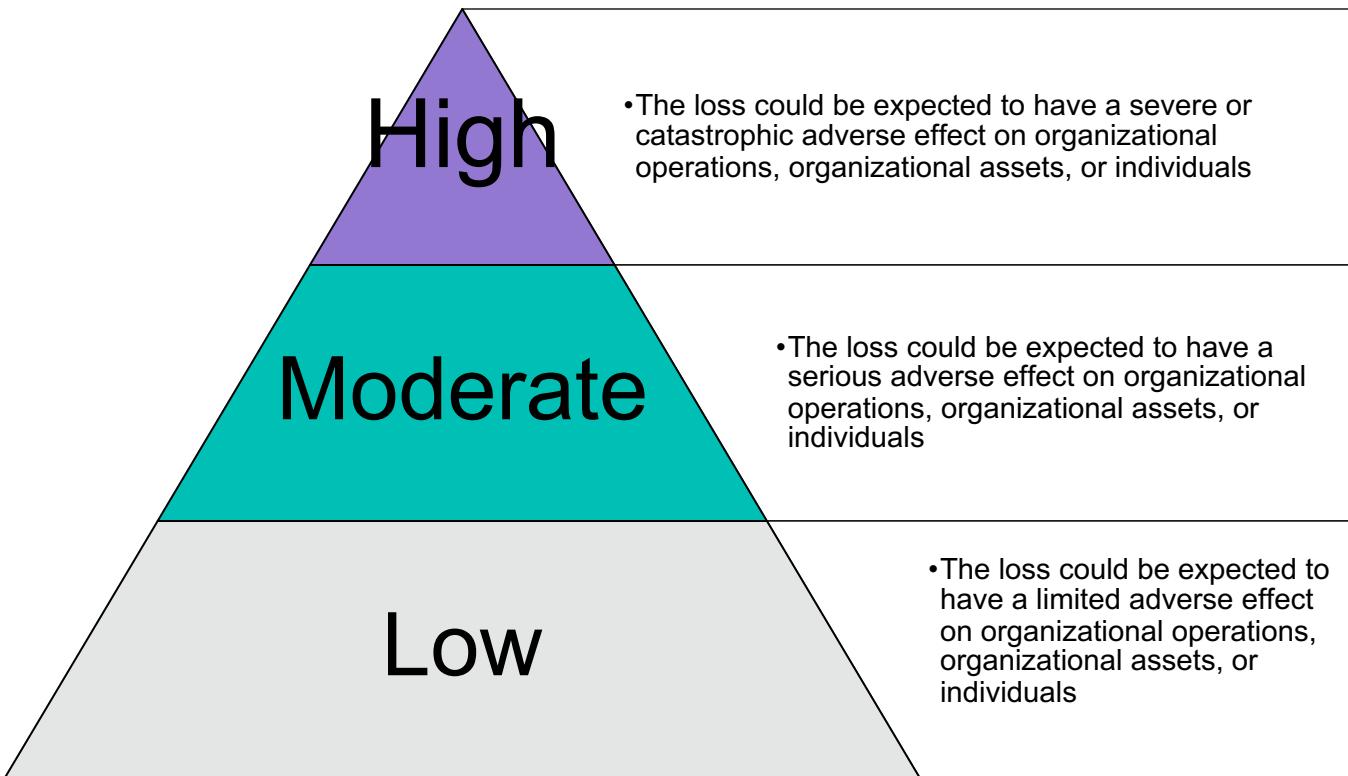

Authenticity

- Verifying that users are who they say they are and that each input arriving at the system came from a trusted source

Accountability

- The security goal that generates the requirement for actions of an entity to be traced uniquely to that entity

Breach of Security Levels of Impact

Computer Security Challenges

- Security is not simple
- Potential attacks on the security features need to be considered
- Procedures used to provide particular services are often counter-intuitive
- It is necessary to decide where to use the various security mechanisms
- Requires constant monitoring
- Is too often an afterthought
- Security mechanisms typically involve more than a particular algorithm or protocol
- Security is essentially a battle of wits between a perpetrator and the designer
- Little benefit from security investment is perceived until a security failure occurs
- Strong security is often viewed as an impediment to efficient and user-friendly operation

OSI Security Architecture

- Security attack
 - Any action that compromises the security of information owned by an organization
- Security mechanism
 - A process (or a device incorporating such a process) that is designed to detect, prevent, or recover from a security attack
- Security service
 - A processing or communication service that enhances the security of the data processing systems and the information transfers of an organization
 - Intended to counter security attacks, and they make use of one or more security mechanisms to provide the service

Security Attacks

- A means of classifying security attacks, used both in X.800 and RFC 4949, is in terms of *passive attacks* and *active attacks*
- A *passive attack* attempts to learn or make use of information from the system but does not affect system resources
- An *active attack* attempts to alter system resources or affect their operation

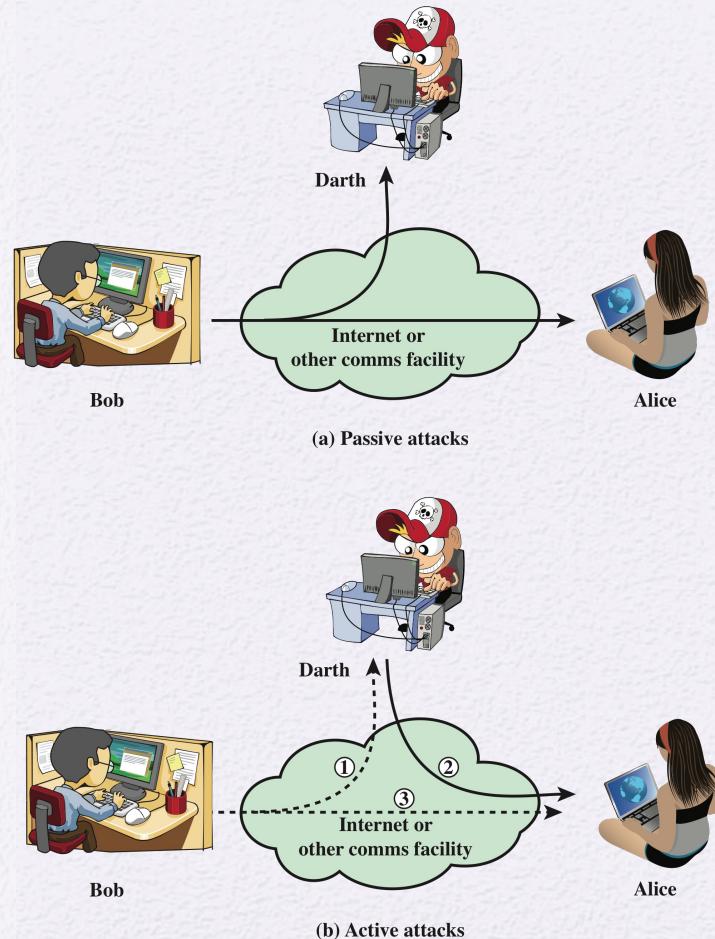

Figure 1.1 Security Attacks

Passive Attacks

- Are in the nature of eavesdropping on, or monitoring of, transmissions
- Goal of the opponent is to obtain information that is being transmitted

- Two types of passive attacks are:
 - The release of message contents
 - Traffic analysis

Active Attacks

- Involve some modification of the data stream or the creation of a false stream
- Difficult to prevent because of the wide variety of potential physical, software, and network vulnerabilities
- Goal is to detect attacks and to recover from any disruption or delays caused by them

Masquerade

- Takes place when one entity pretends to be a different entity
- Usually includes one of the other forms of active attack

Replay

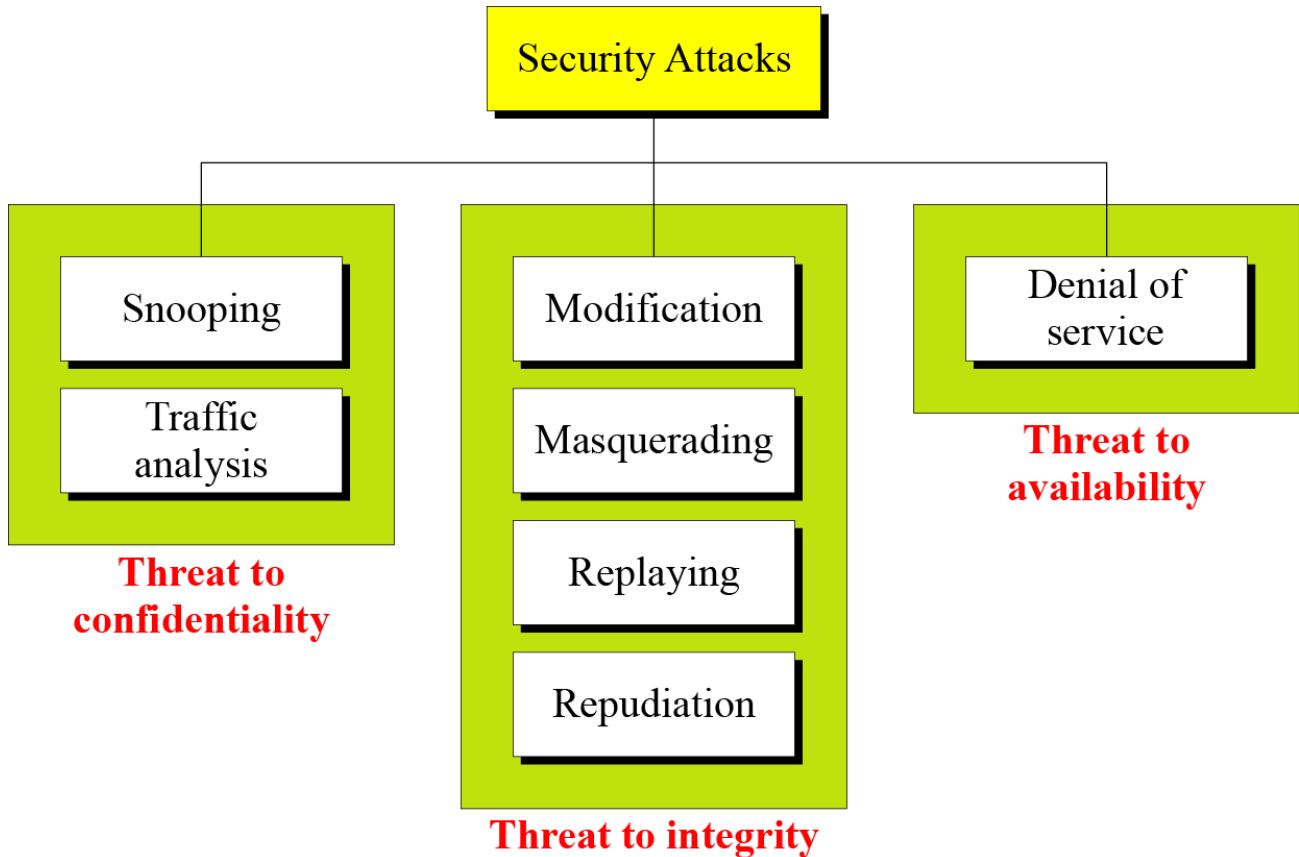

- Involves the passive capture of a data unit and its subsequent retransmission to produce an unauthorized effect

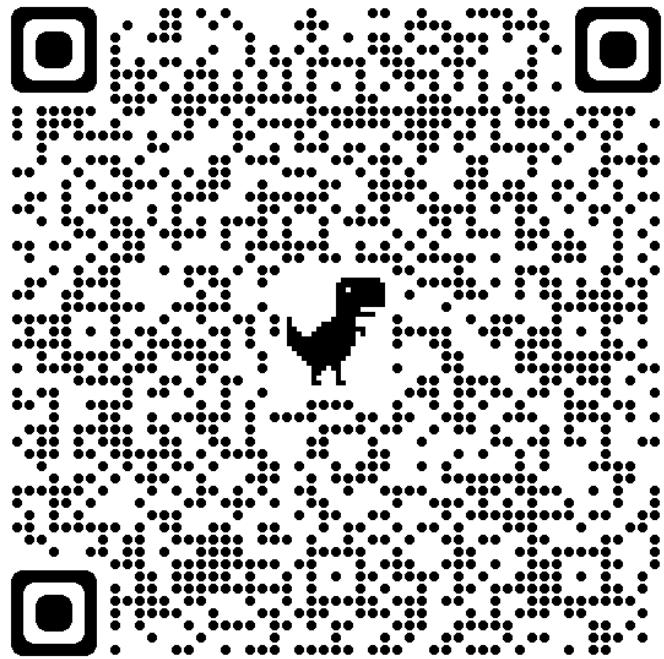

Modification of messages

- Some portion of a legitimate message is altered, or messages are delayed or reordered to produce an unauthorized effect

Denial of service

- Prevents or inhibits the normal use or management of communications facilities

Authentication:

Or who are you?

Authorization:

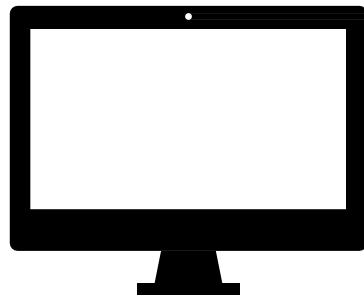

Or what can you do?

Accountability:

Or who did what?

Authentication

Who are you?

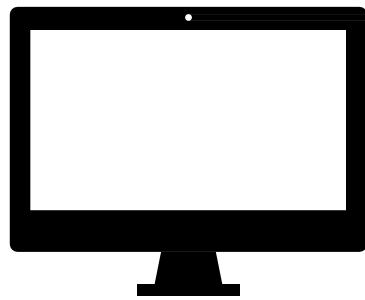

I am Alma and I'd like to
use this computer...

Authentication

Who are you?

Authentication

- Concerned with assuring that a communication is authentic
 - In the case of a single message, assures the recipient that the message is from the source that it claims to be from
 - In the case of ongoing interaction, assures the two entities are authentic and that the connection is not interfered with in such a way that a third party can masquerade as one of the two legitimate parties

Two specific authentication services are defined in X.800:

- Peer entity authentication
- Data origin authentication

Authentication

3 Basic Mechanisms

Something you know

- Passwords

Something you have

- Keys

Something you are

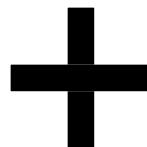

- Biometrics and behaviours

Authentication

3 Basic Mechanisms

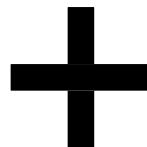

Something you know

Authentication Keys

Something you have!

Typically a digital signature of some kind...

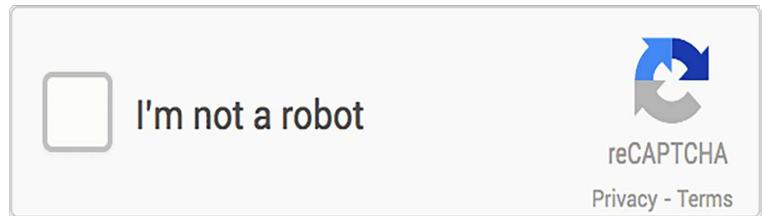

- PGP is hard (-ish)

What happens if you lose it?

Authentication

Biometrics

Something you are!

Track something about a person...

- Gait... mouse movements... usage patterns
 - Build a machine learning model about it
-
- How do you repudiate your fingerprints?
 - How do you handle accessibility?

Authentication Federated Identity Management

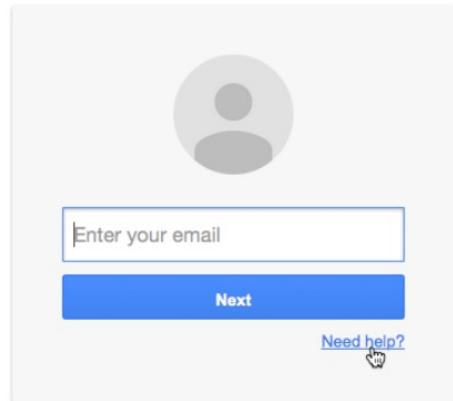

Delegate to someone else for your identity management!

- Great for organisations
 - ...centralised employee management!
- Great for amateur developers
 - ...less to get wrong/GDPR compliance!
- Bad for privacy
 - ...if you lose access to your Google account you lose access to **EVERY** connected service.

Kerberos, LDAP OAuth2...

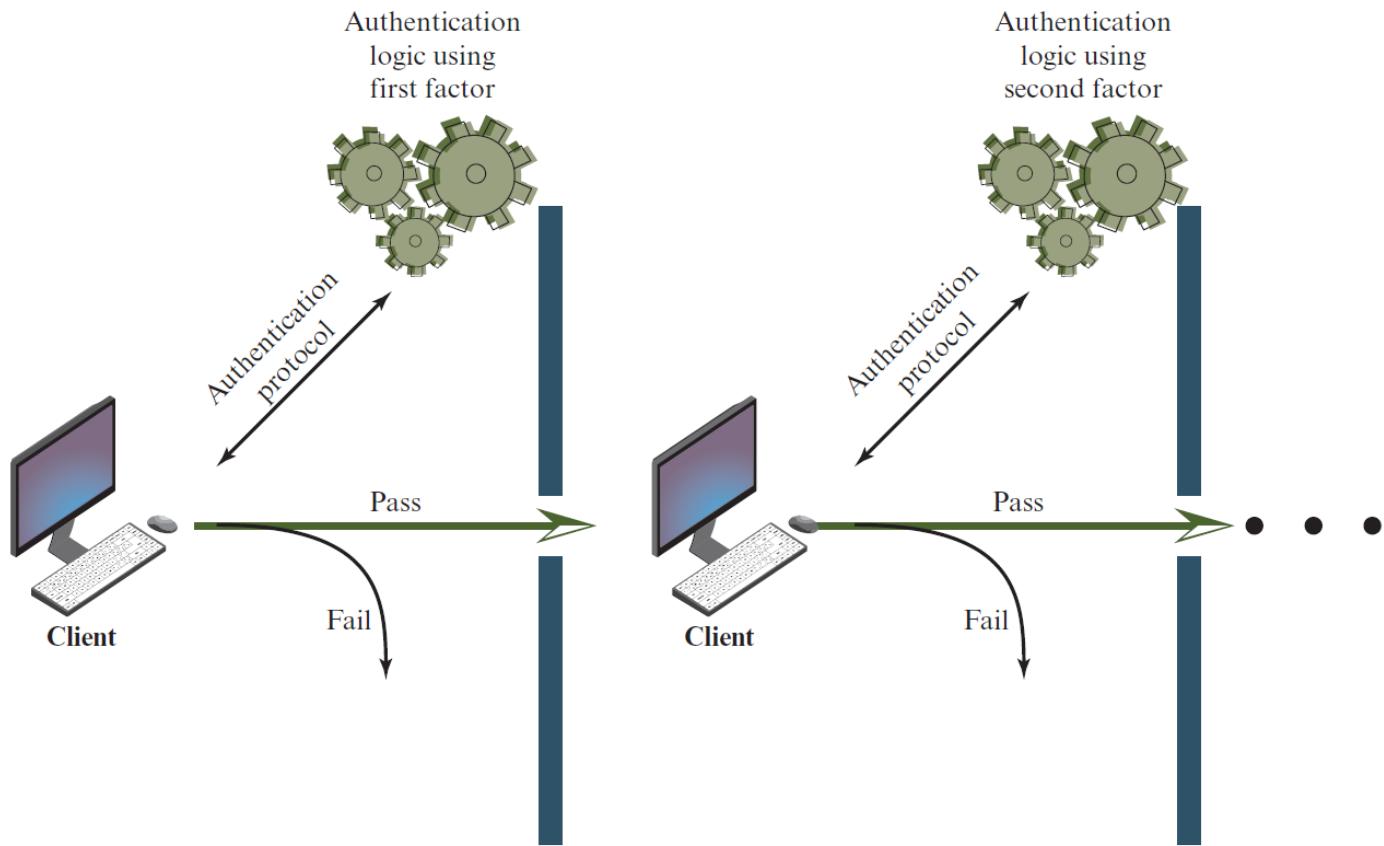

One account. All of Google.

Sign in with your Google Account

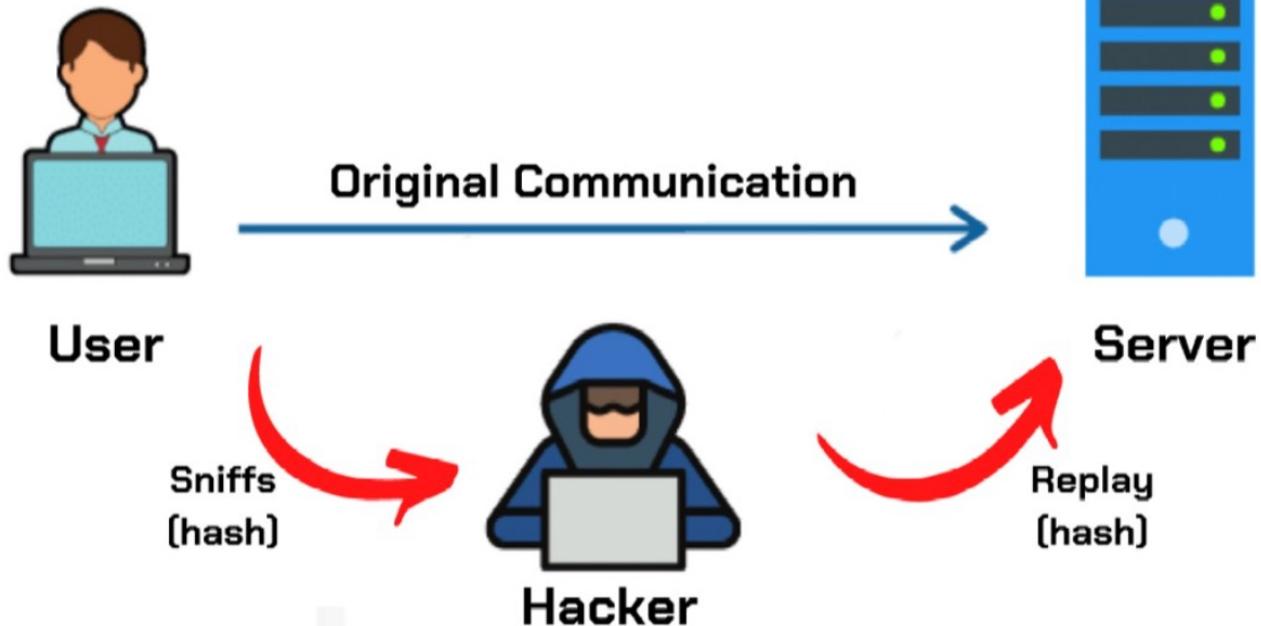

Authentication factors

Factor	Examples	Properties
Knowledge	User ID Password PIN	Can be shared Many passwords easy to guess Can be forgotten
Possession	Smart Card Electronic Badge Electronic Key	Can be shared Can be duplicated (cloned) Can be lost or stolen
Inherence	Fingerprint Face Iris Voice print	Not possible to share False positives and false Negatives possible Forging difficult

What can go wrong?

Replay attack

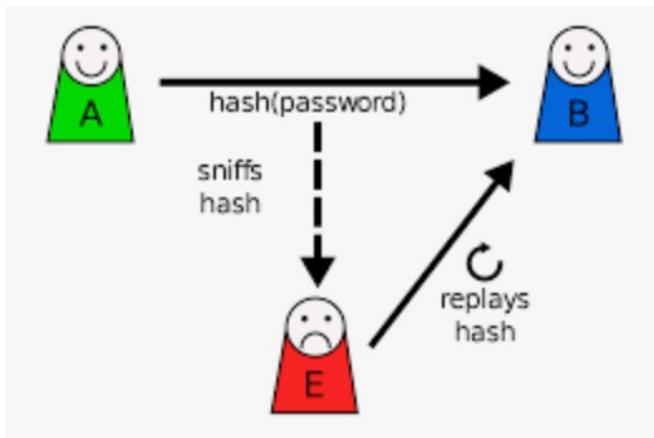

Replay attack

The simplest replay attack is one in which the opponent simply **copies a message** and **replays it later**.

An opponent can replay a **timestamped** message within the valid **time window**.

An opponent can replay a timestamped message within the valid time window, but in addition, the opponent suppresses the original message; thus, the **repetition cannot be detected**.

Another attack involves a **backward replay** without modification and is possible if symmetric encryption is used and the sender cannot easily recognize the difference between messages sent and messages received on the basis of content.

Impersonation attack

Cybercriminals usually **replay authentication sessions**, which give attackers full control of your accounts and all the privileges you enjoy on specific websites or apps.

They can **impersonate you online, send and receive messages on your behalf, and access confidential data or documents.**

A real story: Impersonation attack against ESET

Cyberattacks can happen to any organization.

In 2020, ESET faced CEO impersonation attempts via WhatsApp messages. The goal of this attempt was to fake the existence of a big bid that required a financial deposit.

Check out samples of these messages below.

Authorization

Distributed Access Control

Sometimes it'd be really nice to get information dynamically from third-parties instead of keeping it locally.

- All *MSc students* can access *MSc Room*
- *MSc manager* can say who's a *MSc Student*
- *Awais* can say whose the *MSc manager*

Bob wants to access the MSc room...

bristol.ac.uk

Accountability:

Or who did what?

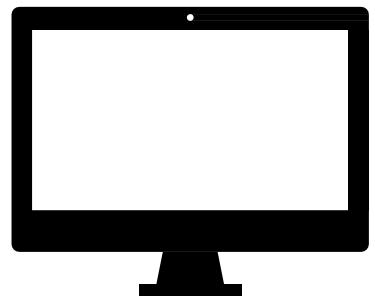

Accountability

Who did what

Accountability

Who did what

A photograph showing a large stack of cut logs, likely from a tree, piled up against a clear blue sky. The logs are arranged in several layers, with their circular cross-sections visible. The wood has a light tan or yellowish-brown color with darker, more weathered areas at the edges and some internal grain patterns.

Logs

Accountability

Logging

Log as much as you can

- But don't be evil

Keep the logs *append* only

- And get them off the machine ASAP
- Hackers like to delete/modify logs

Standard-ish log formats

```
127.0.0.1 [01/Dec/2020:13:55:36 -0000] "GET /slides HTTP/1.0" 200 4007
```

bristol.ac.uk

Accountability

Proof Carrying Code / Digital Evidence

Suppose I have some authorisation logic making decisions about who I let in...

Deriving a proof that someone is allowed in can take a lot of time...

But checking a proof can usually be done quickly!
